Measuring Low-Value Care in Medicare

Aaron L. Schwartz, BA; Bruce E. Landon, MD, MBA; Adam G. Elshaug, PhD, MPH; Michael E. Chernew, PhD; J. Michael McWilliams, MD, PhD

IMPORTANCE Despite the importance of identifying and reducing wasteful health care use, few direct measures of overuse have been developed. Direct measures are appealing because they identify specific services to limit and can characterize low-value care even among the most efficient providers.

OBJECTIVES To develop claims-based measures of low-value services, examine service use (and associated spending) detected by these measures in Medicare, and determine whether patterns of use are related across different types of low-value services.

DESIGN, SETTING, AND PARTICIPANTS Drawing from evidence-based lists of services that provide minimal clinical benefit, we developed 26 claims-based measures of low-value services. Using 2009 claims for 1 360 908 Medicare beneficiaries, we assessed the proportion of beneficiaries receiving these services, mean per-beneficiary service use, and the proportion of total spending devoted to these services. We compared the amount of use and spending detected by versions of these measures with different sensitivity and specificity. We also estimated correlations between use of different services within geographic areas, adjusting for beneficiaries' sociodemographic and clinical characteristics.

MAIN OUTCOMES AND MEASURES Use and spending detected by 26 measures of low-value services in 6 categories: low-value cancer screening, low-value diagnostic and preventive testing, low-value preoperative testing, low-value imaging, low-value cardiovascular testing and procedures, and other low-value surgical procedures.

RESULTS Services detected by more sensitive versions of measures affected 42% of beneficiaries and constituted 2.7% of overall annual spending. Services detected by more specific versions of measures affected 25% of beneficiaries and constituted 0.6% of overall spending. In adjusted analyses, low-value spending detected in geographic regions at the 5th percentile of the regional distribution of low-value spending (\$227 per beneficiary) exceeded the difference in detected low-value spending between regions at the 5th and 95th percentiles (\$189 per beneficiary). Adjusted regional use was positively correlated among 5 of 6 categories of low-value services (mean r for pairwise, between-category correlations, 0.33; range, 0.14–0.54; $P \leq .01$).

CONCLUSIONS AND RELEVANCE Services detected by a limited number of measures of low-value care constituted modest proportions of overall spending but affected substantial proportions of beneficiaries and may be reflective of overuse more broadly. Performance of claims-based measures in supporting targeted payment or coverage policies to reduce overuse may depend heavily on how the measures are defined.

Several recent initiatives, including the Choosing Wisely campaign by the American Board of Internal Medicine Foundation,¹ have focused on directly defining wasteful health care services that provide little or no health benefit to patients. It is challenging, however, to translate evidence-based lists of low-value services generated by such initiatives into meaningful metrics that can be applied to available data sources, such as insurance claims.² The value of most services depends on the clinical situation in which they are provided, and administrative data often lack the clinical detail necessary to distinguish appropriate from inappropriate use. Consequently, the number of low-value services that can be reliably identified in claims data may be limited, and the amount of low-value care detected by claims-based measures may be highly sensitive to how the measures are defined.

Direct approaches to measuring overuse may nevertheless be useful for characterizing the potential extent of wasteful care and informing policies to address low-value practices. Indirect approaches to measuring care efficiency, such as comparing total risk-adjusted spending per patient across geographic areas or provider organizations,³ may be challenging for policy makers and providers to act on because specific services contributing to wasteful spending are not identified.⁴ Furthermore, such relative measures may fail to characterize the full extent of low-value practices if they are widespread. In contrast, direct measures could be used to identify specific instances of overuse and assess their frequency among even the most efficient providers. In addition, even a limited set of direct measures could be useful for monitoring low-value care if it reflects underlying drivers of overuse more broadly. For analogous reasons, many quality measures relating to underuse have been developed and applied widely in quality improvement initiatives despite similar measurement challenges.^{5,6}

Drawing from evidence-based lists and the medical literature, we created algorithms to measure selected low-value services that could be applied to insurance claims data with reasonable accuracy despite the limited clinical information in claims. Using 2009 Medicare claims, we examined the use of these services and their associated spending, varying the sensitivity and specificity with which the measures likely identified overuse. We also examined whether use of different types of low-value care was correlated within regions; positive correlations might suggest that the measures reflect common drivers of overuse.

Methods

Data Sources and Sample Population

We analyzed 2008-2009 claims data for a random 5% sample of Medicare beneficiaries, as well as demographic information from enrollment files and chronic conditions from the Chronic Conditions Data Warehouse (CCW).⁷ We applied measures of low-value services to 2009 claims, using 2008 claims and the CCW for relevant clinical history. Our study population consisted of 1 360 908 beneficiaries

who were continuously enrolled in Parts A and B of traditional fee-for-service Medicare in 2008 and while alive in 2009. We further restricted the study population to individuals who, in 2009, were living in the United States or Washington, DC, and were at least 65 years old. Our study was approved by the Harvard Medical School Committee on Human Studies and the Privacy Board of the Centers for Medicare & Medicaid Services.

Measures of Low-Value Services

We considered services that have been characterized as low value by the American Board of Internal Medicine Foundation's Choosing Wisely initiative,⁸ the US Preventive Services Task Force "D" recommendations,⁹ the National Institute for Health and Care Excellence "do not do" recommendations,¹⁰ the Canadian Agency for Drugs and Technologies in Health health technology assessments,¹¹ or peer-reviewed medical literature.¹² These services have been found to provide little to no clinical benefit on average, either in general or in specific clinical scenarios. From these services, we selected a subset that is relevant to the Medicare population and could be detected using Medicare claims with reasonable specificity, meaning that major clinical factors distinguishing likely overuse from appropriate use could be identified or approximated with claims and enrollment data (eAppendix in the Supplement). We also required the evidence base characterizing each service as low value to have been established before 2009. Many low-value services were not selected (eg, imaging for pulmonary embolism without moderate or high pretest probability⁸) because of difficulty distinguishing inappropriate from appropriate use with claims data.

For each selected service, we developed an operational definition of low-value occurrences using *Current Procedural Terminology* (CPT) codes, Berenson-Eggers Type of Service codes, *International Classification of Diseases, Ninth Revision* diagnostic codes, CCW indicators, timing of care, site of care, and demographic information (eTable 1 in the Supplement). When supported by clinical evidence or guidelines, we broadened the scope of some recommendations featured in lists of low-value services. For example, we expanded the Choosing Wisely definition of low-value preoperative pulmonary testing before cardiac surgery to include preoperative pulmonary testing before low- or intermediate-risk surgical procedures more broadly.¹³ We also combined similar low-value services (eg, various laboratory tests for hypercoagulable states) into single measures. **Table 1** presents the operational definitions for the 26 measures of low-value care we developed and applied to claims.

Inherent in most of our claims-based measures of low-value care was a trade-off between sensitivity (greater capture of inappropriate use) and specificity (less misclassification of appropriate use as inappropriate). To assess the variability of our findings across a spectrum of these important measurement properties, we specified 2 versions of each measure, one with higher sensitivity (and lower specificity) and the other with higher specificity (and lower sensitivity) for detecting low-value care (Table 1). Even without a gold standard for assessing service appropriateness, the relative

Table 1. Measures of Low-Value Services

Measure	Source and Supporting Literature	Operational Definition	
		More Sensitive, Less Specific (Base Definition)	Less Sensitive, More Specific (Additional Restrictions)
Cancer Screening			
Cancer screening for patients with CKD receiving dialysis	CW ¹⁴	Screening for cancer of the breast, cervix, colon, or prostate for patients with CKD receiving dialysis services	Only patients aged ≥75 y ^a
Cervical cancer screening for women aged ≥65 y	CW, USPSTF ¹⁵	Screening Papanicolaou test for women aged ≥65 y	No personal history of cervical cancer or dysplasia noted in claim or in prior claims ^b ; no diagnoses of other female genital cancers, abnormal Papanicolaou findings, or human papillomavirus positivity in prior claims
Colorectal cancer screening for older elderly patients	USPSTF ¹⁶	Colorectal cancer screening (colonoscopy, sigmoidoscopy, barium enema, or fecal occult blood testing) for patients aged ≥75 y	No history of colon cancer; only screening (ie, not diagnostic) procedure codes; only patients aged ≥85 y
PSA testing for men aged ≥75 y	USPSTF ¹⁷	PSA test for patients aged ≥75 y	No history of prostate cancer; only screening (ie, not diagnostic) procedure codes
Diagnostic and Preventive Testing			
Bone mineral density testing at frequent intervals	Literature ^{18,19}	Bone mineral density test <2 y after prior bone mineral density test	Only patients with a diagnosis of osteoporosis before initial bone mineral density test ^c
Homocysteine testing for cardiovascular disease	Literature ²⁰	Homocysteine testing	No diagnoses of folate or B12 deficiencies in claim and no folate or B12 testing in prior claims
Hypercoagulability testing for patients with deep vein thrombosis	CW ²¹	Laboratory tests for hypercoagulable states within 30 d after diagnosis of lower-extremity deep vein thrombosis or pulmonary embolism	No evidence of recurrent thrombosis, defined by diagnosis of deep vein thrombosis or pulmonary embolism >90 d before claim
PTH measurement for patients with stage 1-3 CKD	NICE ^{22,23}	PTH measurement in patients with CKD	No dialysis services before PTH testing or within 30 d after testing; no hypercalcemia diagnosis in any 2009 claim
Preoperative Testing			
Preoperative chest radiography	CADTH, CW ^{24,25}	Chest radiograph specified as a preoperative assessment or occurring within 30 d before a low- or intermediate-risk noncardiothoracic surgical procedure ^d	No radiographs related to inpatient or emergency care ^e ; only radiographs that preceded a low- or intermediate-risk noncardiothoracic surgical procedure (ie, excluding those specified as preoperative before other procedures) ^d
Preoperative echocardiography	CW ²⁶	Echocardiogram specified as a preoperative assessment or obtained within 30 d before a low- or intermediate-risk noncardiothoracic surgical procedure ^d	No echocardiograms related to inpatient or emergency care ^e ; only echocardiograms that preceded a low- or intermediate-risk noncardiothoracic surgical procedure ^d
Preoperative PFT	CW ¹³	PFT specified as a preoperative assessment or occurring within 30 d before a low- or intermediate-risk surgical procedure ^f	No PFT related to inpatient or emergency care ^e ; only PFT that preceded a low- or intermediate-risk surgical procedure ^f
Preoperative stress testing	CW ²⁷	Stress electrocardiography, echocardiography, or nuclear medicine imaging specified as a preoperative assessment or occurring within 30 d before a low- or intermediate-risk noncardiothoracic surgical procedure ^d	No stress testing related to inpatient or emergency care ^e ; only stress testing that preceded a low- or intermediate-risk noncardiothoracic surgical procedure ^d
Imaging			
CT of the sinuses for uncomplicated acute rhinosinusitis	CW ²⁸	Maxillofacial CT study with a diagnosis of sinusitis in the imaging claim	No complications of sinusitis, ^g immune deficiencies, nasal polyps, or head/face trauma noted in claim; no patients with chronic sinusitis, defined by sinusitis diagnosis between 1 y and 30 d before imaging
Head imaging in the evaluation of syncope	CW, NICE ²⁹	CT or MR imaging of the head with a diagnosis of syncope in the imaging claim	No diagnoses in claim warranting imaging ^h
Head imaging for uncomplicated headache	CW ³⁰	CT or MR imaging of the head with a diagnosis of (nonthunderclap, nonposttraumatic) headache	No diagnoses in claim warranting imaging ⁱ
EEG for headaches	CW ³¹	EEG with headache diagnosis in the claim	No epilepsy or convulsions noted in current or prior claims
Back imaging for patients with nonspecific low back pain	CW, NICE ³²	Back imaging with a diagnosis of lower back pain	No diagnoses in claim warranting imaging ^j ; imaging occurred within 6 wk of the first diagnosis of back pain
Screening for carotid artery disease in asymptomatic adults	CW, USPSTF ³³	Carotid imaging for patients without a history of stroke or TIA and without a diagnosis of stroke, TIA, or focal neurological symptoms in claim	Test not associated with inpatient or emergency care ^k

(continued)

Table 1. Measures of Low-Value Services (continued)

Measure	Source and Supporting Literature	Operational Definition	
		More Sensitive, Less Specific (Base Definition)	Less Sensitive, More Specific (Additional Restrictions)
Screening for carotid artery disease for syncope	CW ²⁹	Carotid imaging with syncope diagnosis	No history of stroke or TIA; no stroke, TIA, or focal neurological symptoms noted in claim
Cardiovascular Testing and Procedures			
Stress testing for stable coronary disease	CW ³⁴ ; literature ³⁵	Stress testing for patients with an established diagnosis of ischemic heart disease or angina (≥6 mo before the stress test) and thus not done for screening purposes	Test not associated with inpatient or emergency care, which might be indicative of unstable angina ^k ; only patients with a past diagnosis of myocardial infarction to exclude patients with a history of noncardiac chest pain inaccurately coded as angina (ie, those with no underlying ischemic heart disease who might benefit from screening and optimization of medical management)
Percutaneous coronary intervention with balloon angioplasty or stent placement for stable coronary disease	Literature ^{35,36}	Coronary stent placement or balloon angioplasty for patients with an established diagnosis of ischemic heart disease or angina (≥6 mo before the procedure); procedure not associated with an ED visit, ^k which might be indicative of acute coronary syndrome	Only patients with a past diagnosis of myocardial infarction to exclude patients with a history of noncardiac chest pain inaccurately coded as angina
Renal artery angioplasty or stenting	Literature ^{37,38}	Renal/visceral angioplasty or stent placement	Diagnosis of renal atherosclerosis or renovascular hypertension noted in procedure claim
Carotid endarterectomy in asymptomatic patients	CW ^{33,39}	Carotid endarterectomy for patients without a history of stroke or TIA and without stroke, TIA, or focal neurological symptoms noted in claim	Operation not associated with an ED visit ^k ; only female patients ^l
IVC filters to prevent pulmonary embolism	Literature ^{40,41}	Any IVC filter placement	No additional restrictions
Other Surgery			
Vertebroplasty or kyphoplasty for osteoporotic vertebral fractures	Literature ⁴²⁻⁴⁵	Vertebroplasty/kyphoplasty for vertebral fracture	No bone cancers, myeloma, or hemangioma noted in procedure claim
Arthroscopic surgery for knee osteoarthritis	NICE ^{46,47}	Arthroscopic debridement/chondroplasty of the knee	Diagnosis of osteoarthritis or chondromalacia in the procedure claim; no meniscal tear noted in the procedure claim

Abbreviations: CADTH, Canadian Agency for Drugs and Technologies in Health health technology assessments; CKD, chronic kidney disease; CT, computed tomography; CW, Choosing Wisely; ED, emergency department; EEG, electroencephalography; IVC, inferior vena cava; MR, magnetic resonance; NICE, National Institute for Health and Care Excellence "do not do" list; PFT, pulmonary function testing; PSA, prostate-specific antigen; PTH, parathyroid hormone; TIA, transient ischemic attack; USPSTF, US Preventive Services Task Force C or D recommendations.

^a This age cutoff is included because the distribution of kidney transplant recipient ages within the sample suggests transplantation is uncommon in patients 75 years or older.

^b Throughout the table, "prior claims" refers to all claims from January 1, 2008, until 1 day before the service of interest.

^c This restriction limits the measure to testing of patients with osteoporosis.

^d Including breast procedures, colectomy, cholecystectomy, transurethral resection of the prostate, hysterectomy, orthopedic surgical procedures other than hip and knee replacement, corneal transplant, cataract removal, retinal detachment, hernia repair, lithotripsy, arthroscopy, and cholecystectomy. The 30-day window between preoperative testing and surgery was derived empirically based on distribution of intervals between test and procedure.

^e Inpatient-associated is defined here as occurring during within 30 days after

an inpatient stay; ED-associated, during or 1 day after an ED visit.

^f Including procedures listed in footnote d as well as coronary artery bypass graft, aneurysm repair, thromboendarterectomy, percutaneous transluminal coronary angioplasty, and pacemaker insertion.

^g Complications of sinusitis include eyelid inflammation, acute inflammation of orbit, orbital cellulitis, and visual problems.

^h Exclusion diagnoses include epilepsy, giant cell arteritis, head trauma, convulsions, altered mental status, nervous system symptoms (eg, hemiplegia), disturbances of skin sensation, speech problems, stroke, transient ischemic attack, and history of stroke.

ⁱ Exclusion diagnoses include those listed in the preceding footnote as well as cancer and history of cancer.

^j Exclusion diagnoses include cancer, trauma, intravenous drug abuse, neurological impairment, endocarditis, septicemia, tuberculosis, osteomyelitis, fever, weight loss, loss of appetite, night sweats, and anemia.

^k Inpatient-associated is defined here as occurring during an inpatient stay; ED-associated, during or within 14 d after an ED visit.

^l Restriction is based on sex-specific subgroup analyses of procedure efficacy in the referenced literature.

sensitivity and specificity of our measures can be inferred from the clinical criteria we applied. For example, limiting the colorectal cancer screening measure to beneficiaries older than 85 years instead of older than 75 years decreases its sensitivity (fewer low-value instances detected) but increases its specificity (smaller proportion of appropriate services misclassified as inappropriate).

We calculated spending on low-value services using standardized prices to adjust for regional differences in Medicare payments. We used the median spending per service nationally as the standardized price for each service, including payments from Medicare, beneficiary coinsurance amounts, and any payments from other primary payers. We included related services typically bundled with the low-value service in

these price estimates (eg, contrast medium administration for an imaging study or anesthesia for a procedure). These bundles were defined based on examination of the most frequent CPT codes appearing during the day a low-value service was provided and thus would not include subsequent care prompted by the service (eg, further imaging for incidental findings on preoperative chest radiographs). Additional information on service detection and pricing, including the specific codes (eg, CPT; Berenson-Eggers Type of Service) used, is available in the eAppendix (Supplement).

Statistical Analysis

We counted the number of times each beneficiary experienced each low-value service and calculated the per-beneficiary spending for each service. From these values, we calculated the percentage of beneficiaries receiving at least 1 low-value service and the aggregate spending for all beneficiaries for each service and in each of 6 service categories: low-value cancer screening; low-value diagnostic and preventive testing; low-value preoperative testing; low-value imaging; low-value cardiovascular testing and procedures; and other low-value surgical procedures. Aggregate spending estimates were multiplied by 20 to approximate spending for the entire Medicare population from 5% samples. We also calculated the proportion of total spending for services covered by Medicare Parts A and B (including coinsurance amounts and payments from other primary payers) devoted to services detected by low-value care measures.

We used hospital referral regions (HRRs) to examine how use of different types of low-value services was related among the same groupings of providers. Although we were not interested in geographic areas per se and although practice patterns vary within and between areas,⁴ HRRs nevertheless served as a useful unit of comparison to determine whether groups of providers that were more likely to provide one type of low-value service were more likely to provide another. First, we estimated mean per-beneficiary utilization counts in each service category at the HRR level using linear regression models with HRR fixed effects. To control for beneficiaries' sociodemographic and clinical characteristics, we included as covariates age, age squared, sex, race, indicators of 21 CCW diagnoses present before 2009 (derived from claims dating back to 1999), indicators of having multiple comorbid conditions (2 to ≥ 7), the Rural-Urban Continuum Code for beneficiaries' county of residence, and several socioeconomic measures of the elderly population at the zip code tabulation area level (median income, percentage below the federal poverty level, and percentage with a high school diploma). To account for additional dimensions of case mix not captured by the CCW, we included indicators of conditions that qualified patients for potential receipt of several low-value services (eg, a diagnosis of headache in 2009 qualifying beneficiaries for potentially inappropriate head imaging; see the eAppendix in the Supplement for details). For each pair of low-value service categories, we then estimated correlations between regional means in adjusted use weighted by the number of traditional fee-for-service Medicare beneficiaries in each HRR. Correlations were not substantially altered by use of random effects

Figure. Utilization Rates and Associated Spending for Services Detected by Low-Value Care Measures Among Medicare Beneficiaries in 2009

Count refers to unique incidences of service provision; overall spending, total spending on all services covered by Medicare Parts A and B (see Table 1 for services included in each category and for operational definitions of all measures).

to estimate regional means or by the addition of indicators of qualifying conditions.

Results

Among 1 360 908 beneficiaries in the study sample, 1 094 374 instances of care provision (80 services per 100 beneficiaries) were detected by the more sensitive measures of low-value services, corresponding to 21.9 million instances for the entire traditional Medicare population in 2009. Forty-two percent of beneficiaries received at least 1 service detected by the more sensitive measures. Our more specific but less sensitive measures of low-value care detected 454 783 services (33 per 100 beneficiaries), corresponding to 9.1 million services for the entire Medicare population. Twenty-five percent of beneficiaries received at least 1 of these services.

Spending for services detected by our more sensitive measures of low-value care totaled \$8.5 billion for the entire Medicare population, or \$310 per beneficiary, whereas spending for services detected by our more specific measures totaled \$1.9 billion, or \$71 per beneficiary. These amounts comprised 2.7% and 0.6%, respectively, of total annual spending in 2009 on services covered by Medicare Parts A and B.

The Figure presents utilization rates and their associated spending, decomposed by category of low-value care measures. Imaging, cancer screening, and diagnostic and preventive testing measures detected most of the use, whereas measures of imaging and cardiovascular testing and procedures detected most of the spending (see eTable 2 in the Supplement for these results in tabular form). Table 2 presents utilization

Abbreviations: Bene, Beneficiaries; CKD, chronic kidney disease; CT, computed tomography; DVT, deep vein thrombosis; EEG, electroencephalography; IVC, inferior vena cava; PBA, proportion of beneficiaries affected; PCI, percutaneous coronary intervention; PFT, pulmonary function testing; PLVC, proportion of low-value count; PLVS, proportion of low-value spending; POS, proportion of overall spending; PSA, prostate-specific antigen; PTH, parathyroid hormone.

^a Count refers to the number of unique incidences of service provision.

^b Overall spending refers to annual spending for services covered by Medicare Parts A and B. See Table 1 for service category assignments and for operational definitions of all measures.

^c Totals do not equal column sums because some patients received multiple services.

rates and associated spending captured by each of the 26 measures of low-value care. Individual measures with major contributions to spending included both high-price, low-use items, such as percutaneous coronary intervention for stable coronary disease, and low-price, high-use items, such as screening for asymptomatic carotid artery disease.

Table 3 presents correlations between adjusted levels of regional service use in different categories of low-value care as detected by our more sensitive measures. Per-beneficiary utilization counts were positively correlated with one another for 5 of the 6 categories. Correlation coefficients ranged from 0.14 to 0.54 across all pairwise combinations of these 5

categories ($P \leq .01$), with a mean of 0.33. Noncardiovascular surgical procedures were not positively correlated with use in other categories of measures. The measures exhibited good internal consistency across all categories (Cronbach $\alpha = 0.68$).

Adjusted regional spending on services detected by more sensitive measures of low-value care ranged from \$227 per beneficiary in the 5th percentile to \$416 per beneficiary in the 95th percentile of HRRs (median, \$304; interquartile range, \$272-\$343). Thus, low-value spending detected in regions at the 5th percentile of the regional distribution exceeded the difference in detected low-value spending between regions at the 5th and 95th percentiles (\$189 per beneficiary).

Discussion

In this national study of selected low-value services, Medicare beneficiaries commonly received care that was likely to provide minimal or no benefit on average. Even when applying narrower versions of our limited number of measures of overuse, we identified low-value care affecting one-quarter of Medicare beneficiaries. These findings are consistent with the notion that wasteful practices are pervasive in the US health care system.

Within regions, different types of low-value use generally exhibited significantly positive correlations with one another, ranging from weak to moderate in strength, although 1 category of low-value use (noncardiovascular surgical procedures) was not positively correlated with the others. These findings suggest that many low-value services may be driven by common factors. Therefore, claims-based measures, although limited in number and the amount of wasteful spending they detect, could be useful for monitoring low-value care more broadly, including some care that may be difficult to measure with claims.

Although these findings suggest that direct approaches to measuring wasteful care may be tractable and informative, other findings underscore potential challenges in developing and applying direct measures of overuse. In particular, the amount of low-value care we detected varied substantially with the clinical specificity of our measures. Estimates of the proportion of Medicare beneficiaries receiving at least 1 measured low-value service decreased from 42% to 25% when we used more restrictive definitions that traded off sensitivity for specificity, and the contribution of low-value spending to total spending decreased from 2.7% to 0.6%. For example, our more sensitive measure of low-value imaging for low back pain captured more inappropriate use of imaging studies at the expense of including some appropriate use. Our more specific measure was less likely to include appropriate use but probably excluded many low-value studies, as suggested by the 3-fold reduction in the number of studies captured.

Thus, the performance of administrative rules to reduce overuse through coverage policy, cost sharing, or value-based payment (eg, pay for performance) may depend heavily on measure definition. Such strategies may be appropriate

for select services whose value is invariably low or whose low-value applications can be identified with high reliability. For other services, however, more sensitive measures could result in unintended restriction of appropriate tests and procedures by coverage and payment policies, whereas more specific measures could substantially limit the effect of these strategies. Provider groups seeking to minimize wasteful spending—for example, in response to global budgets—may be able to distinguish appropriate from inappropriate practices at the point of care without having to use rigid rules derived from incomplete clinical data.

We also found that, although spending on low-value services varied considerably across regions, spending on low-value services was substantial even in regions where it was lowest. For example, low-value spending at the 5th percentile of the regional distribution of low-value spending was greater than the difference in low-value spending between the 5th and 95th percentiles. This finding suggests potential advantages of direct measurement over relative spending comparisons as a basis for detecting overuse because overuse may be substantial even among more efficient providers.

Our study has several limitations. Most notably, we analyzed only 26 measures of low-value services. In selecting these measures, we emphasized the specificity with which overuse could be detected with claims data and created more restrictive versions that limited contributions of potentially valuable service use to low-value spending totals and utilization counts. Despite the limited number of services we examined, their frequency and correlations with one another suggest substantial and widespread wasteful care. Use of a broader set of less specific and more sensitive measures would capture more low-value care. Similarly, broader definitions of wasteful spending that include downstream costs of low-value service use (eg, repeat imaging for incidental findings) would capture more spending than our measures did. For example, one study estimated that testing costs may account for just 2% of the lifetime costs of prostate-specific antigen screening.⁴⁸

Clinical data from linked medical records might support a more extensive assessment of the properties of claims-based measures. However, we would not expect the incorporation of more detailed data to substantially alter the amount of low-value care captured by many of our measures (eg, cancer screening in patients above certain ages, inappropriately

frequent bone mineral density testing, homocysteine testing for cardiovascular disease, renal artery stenting, and vertebroplasty). Furthermore, by varying the definitions of our measures, we were able to demonstrate potential limitations of claims-based measures without having to use medical record data; any inconsistencies between claims and medical records in the amount of low-value care detected would have similar implications for strategies to address wasteful practices. Moreover, we focused on the potential utility of claims-based measures because medical record review as a means to measure and monitor wasteful care is costly and thus not feasible on a large scale. Nevertheless, validation of claims-based measures against a gold standard of clinical appropriateness will be needed to more precisely define their strengths and weaknesses and assess their utility for different purposes, such as monitoring, profiling, payment policy, or coverage design.

Although our analysis suggests that common drivers of low-value care exist, our study did not identify specific determinants of wasteful care. Factors associated with low-value care may also be associated with high-value care.^{49,50} Coupling measures of overuse with measures of underuse may therefore be important when evaluating programs intended to achieve more cost-effective care.

Finally, unmeasured variation in diagnostic coding practices or case mix may have contributed to positive correla-

tions between regional use of different low-value services in our study. These were not likely sources of significant bias, however, because we found a significant positive correlation between categories of low-value services that did not rely on diagnosis codes to define (ie, age-inappropriate cancer screening and preoperative testing) and because our results were not sensitive to adjustment for additional conditions qualifying beneficiaries for potential receipt of several low-value services.

Conclusions

Many quality measures have been developed to assess underuse but few to assess overuse. Our study findings illustrate the potential utility and limitations of a direct approach to detect wasteful care. Despite their imperfections, claims-based measures of low-value care could be useful for tracking overuse and evaluating programs to reduce it. However, many direct claims-based measures of overuse may be insufficiently accurate to support targeted coverage or payment policies that have a meaningful effect on use without resulting in unintended consequences. Broader payment reforms, such as global or bundled payment models, could allow greater provider discretion in defining and identifying low-value services while incentivizing their elimination.

ARTICLE INFORMATION

Accepted for Publication: February 7, 2014.

Published Online: May 12, 2014.

doi:10.1001/jamainternmed.2014.1541.

Author Contributions: Mr Schwartz and Dr McWilliams had full access to all the data in the study and take responsibility for the integrity of the data and the accuracy of the data analysis.

Study concept and design: All authors.

Acquisition of data: Schwartz, McWilliams.

Analysis and interpretation of data: Elshaug, Chernew, McWilliams.

Drafting of the manuscript: Schwartz, Elshaug, McWilliams.

Critical revision of the manuscript for important intellectual content: All authors.

Statistical analysis: Schwartz, McWilliams.

Obtained funding: McWilliams.

Administrative, technical, or material support: Schwartz, McWilliams.

Study supervision: Elshaug, Chernew, McWilliams.

Conflict of Interest Disclosures: Dr Chernew reports that he is a partner in VBI Health, LLC, which has a contract with Milliman to develop and market a tool to help insurers and employers quantify spending on low-value services. Dr Elshaug reports that he provides advice to the Australian Government Department of Health on policy responses to low-value health care. Mr Schwartz and Drs Landon and McWilliams report no conflicts.

Funding/Support: This work was supported by grants from the Beeson Career Development Award Program (National Institute on Aging grant K08 AG038354 and the American Federation for Aging Research), the Doris Duke Charitable Foundation (Clinical Scientist Development Award 2010053), the National Institute on Aging (grant P01

AG032952), the Agency for Healthcare Research and Quality (Institutional Training Grant 2T32HS000055-20), Harvard University (Christopher G. P. Walker Fellowship), and the Australian National Health and Medical Research Council (Sidney Sax Public Health Fellowship 627061).

Role of the Sponsor: The funding sources did not play a role in the design and conduct of the study; collection, management, analysis, and interpretation of the data; preparation, review, and approval of the manuscript; or decision to submit the manuscript for publication.

Additional Contributions: We are grateful to Joseph P. Newhouse, PhD, and Frank Levy, PhD, for comments on an earlier draft of the manuscript. Drs Newhouse and Levy were not compensated for their contributions.

Editor's Note

Developing Methods for Less Is More

Mitchell H. Katz, MD; Deborah Grady, MD, MPH; Rita F. Redberg, MD, MSc

We have been very gratified by the response of our readers to our Less Is More series. Physicians and patients have endorsed the need to eliminate medical practices that confer no benefit but have true risks.

Related article page 1067

For the field to move forward, however, we need better ways to measure unnecessary care. In that spirit, we thought that this article by Schwartz et al¹ was an important contribution. The authors developed a list of 26 measures of low-value care that could be

assessed using claims data and then applied them to a large sample of Medicare recipients. Depending on the level of sensitivity used, their measures identified 25% to 42% of beneficiaries as having received low-value care. This article highlights the opportunity for eliminating unnecessary care, and we hope that others will use and improve the methods developed by the authors. Most important, we hope that development of better measures of low-value care will ultimately spur development of interventions to reduce unnecessary care.
