Analysis of Gestational Weight Gain During the COVID-19 Pandemic in the US

Wangnan Cao, PhD; Shengzhi Sun, PhD; Valery A. Danilack, MPH, PhD

Introduction

The COVID-19 pandemic has been associated with weight gain among adults, children, and adolescents, but little is known about gestational weight gain (GWG) among pregnant individuals. Gestational weight gain is associated with important health implications for parents and offspring, and excessive GWG is associated with adverse pregnancy outcomes. We estimated changes in GWG among individuals giving birth to live infants during the COVID-19 pandemic in the US.

Methods

In this cross-sectional study, we obtained data on all live births in the US from January 1, 2018, to December 31, 2020, from the National Center for Health Statistics of the Centers for Disease Control and Prevention. Data analysis was performed from January 1, 2022, to July 15, 2022. We restricted our analyses to singleton births to residents and excluded births with missing gestational age, GWG, and body mass index (BMI; calculated as weight in kilograms divided by height in meters squared) before pregnancy. Gestational weight gain was calculated by subtracting weight before pregnancy from the delivery weight. To examine vulnerable racial and ethnic groups, race and ethnicity were categorized on the basis of US birth certificate questionnaires as Hispanic, non-Hispanic Asian or non-Hispanic Pacific Islander, non-Hispanic Black, non-Hispanic White, and other race or ethnicity (including non-Hispanic American Indian or Alaskan Native, non-Hispanic with more than 1 race, and unknown or undisclosed race or ethnicity). Patient consent was waived because the study involved analysis of deidentified publicly available data and was deemed non–human participant research by the institutional review board at the Capital Medical University. This study followed the STROBE reporting guideline.

We defined the COVID-19 pandemic period as March 1 to December 31, 2020. We defined dichotomous excessive GWG as weight gain above the BMI-specific Institute of Medicine recommendations. We used linear regression or logistic regression to compare the GWG (continuous outcome) or excessive GWG (dichotomous outcome) among patients whose infants were born during the pandemic period vs the analogous period in 2019 (ie, referent period) after excluding prepandemic trends in GWG by comparing GWG or excessive GWG during the referent period in 2019 vs 2018 (eAppendix in the Supplement). We adjusted for gestational age, maternal age, educational attainment, race and ethnicity, marital status, adequacy of prenatal care utilization index, BMI before pregnancy, and source of delivery payment. Analyses were performed in R software, version 3.6.1 (R Foundation for Statistical Computing). A 2-sided \( P < .05 \) was considered statistically significant.

Results

Our analysis included 2,847,592 singleton births in 2020 (mean [SD] GWG, 13.31 [6.85] kg), 2,475,822 in 2019 (mean [SD] GWG, 13.28 [6.84] kg), and 2,847,592 in 2018 (mean [SD] GWG, 13.31 [6.85] kg) (Table 1). After adjusting for covariates and excluding prepandemic trends in GWG, we observed an increase of 0.06 kg (95% CI, 0.04-0.07 kg) in GWG, with pronounced increases among pregnant

Abbreviations: APNCU, adequacy of prenatal care utilization; BMI, body mass index (calculated as weight in kilograms divided by height in meters squared).
* We mutually adjusted all variables in the table in linear regressions.
* Net changes during the pandemic were calculated as GWG for 2020 vs 2019 minus GWG for 2019 vs 2018, and the corresponding 95% CIs were calculated as the square root of the sum of the squares of the separate SEs.
* Includes non-Hispanic American Indian or Alaskan Native, non-Hispanic with more than 1 race, and unknown or undisclosed race or ethnicity.

Abbreviations: APNCU, adequacy of prenatal care utilization; BMI, body mass index (calculated as weight in kilograms divided by height in meters squared); NA, not applicable; OR, odds ratio.

* Excessive gestational weight gain was defined as weight gain above the BMI-specific Institute of Medicine recommendations.

b We mutually adjusted all covariates in the table in logistic regressions.

c Log ORs were calculated as log gestational weight gain for 2020 vs 2019 minus log gestational weight gain for 2019 vs 2018, and the corresponding SEs were calculated as the square root of the sum of the squares of the separate logs of SEs.

d *P < .05 indicates statistically significant log OR (at 5% level) compared with the reference group.

e Includes non-Hispanic American Indian or Alaskan Native, non-Hispanic with more than 1 race, and unknown or undisclosed race or ethnicity.

f The APNCU index was calculated based on the month in which prenatal care is initiated and the number of visits from initiation of care until delivery. It is categorized into 4 levels: (1) inadequate care is defined as starting prenatal care after the fourth month of pregnancy or receiving less than 50% of expected visits based on the schedule of prenatal care visits recommended by American College of Obstetricians and Gynecologists; (2) intermediate care is care begun by month 4 with 50% to 79% of expected visits received; (3) adequate care is begun by month 4 with 80% to 109% of expected visits received; and (4) adequate plus care is begun by month 4 with 110% or more of expected visits received.
individuals younger than 25 years (net change, 0.22; 95% CI, 0.19-0.26), non-Hispanic Black individuals (net change, 0.12; 95% CI, 0.07-0.16), unmarried individuals (net change, 0.16; 95% CI, 0.13-0.19), individuals who had obesity before pregnancy (net change, 0.17; 95% CI, 0.14-0.21), and individuals who used Medicaid to pay for delivery (net change, 0.17; 95% CI, 0.15-0.20) (Table 1). The pandemic was also associated with an increased risk of excessive GWG (ratio of odds ratio, 1.01; 95% CI, 1.01-1.02) (Table 2). The susceptible populations to excessive GWG were the same as for continuous GWG.

Discussion

These findings suggest that the COVID-19 pandemic was associated with higher GWG and higher risk of excessive GWG among US individuals with singleton pregnancies, especially those younger than 25 years, non-Hispanic Black individuals, unmarried individuals, individuals with obesity before pregnancy, and individuals using Medicaid to pay for delivery. These findings shed light on the associations of the pandemic with adverse pregnancy outcomes and highlight the need to address pandemic-related GWG, particularly among vulnerable populations, to minimize the public health impact. Study limitations include self-reported height and weight before pregnancy and lack of information on COVID-19 infection on birth certificates. Future studies that identify the period of maximum association of the COVID-19 pandemic with GWG may be useful.
