Mental Health Status Among Children in Home Confinement During the Coronavirus Disease 2019 Outbreak in Hubei Province, China

As the coronavirus disease 2019 (COVID-19) epidemic progressed in Wuhan, Hubei province, China, the Chinese government ordered a nationwide school closure. More than 180 million students in China were restricted to their homes (<http://www.chinanews.com/sh/2020/02-17/9094648.shtml>). The COVID-19 infection has become a global pandemic. As of April 9, 2020, the infection has caused 188 countrywide closures around the world and has affected 1 576 021 818 learners (<https://zh.unesco.org/themes/education-emergencies/coronavirus-school-closures>). The caution about protecting the mental health of children in home confinement is warranted. This study investigated depressive and anxiety symptoms among students in Hubei province, China, which can help optimize interventions on the mental health of children for stakeholders in all countries affected by COVID-19.

Methods | In Hubei province, students in Wuhan were restricted to home from January 23, 2020, and those in Huangshi (a city about 52 mi [85 km] from Wuhan) started observing the restrictions on January 24, 2020. The students in the city of Huangshi remained at home until March 23, 2020, and those in Wuhan until April 8, 2020. A total of 2330 students in grades 2 through 6 in 2 primary schools in Hubei province, of whom 845 were from Wuhan and 1485 were from Huangshi, were invited to complete a survey between February 28 and March 5, 2020. This study was approved by the Ethics Committee of Tongji Medical College, Huazhong University of

Table 1. Characteristics of Participants

Characteristic	Participants, No. (%)
Sex	
Male	1012 (56.7)
Female	772 (43.3)
Location of school	
Huangshi	1109 (62.2)
Wuhan	675 (37.8)
Grade	
2	373 (20.9)
3	329 (18.4)
4	406 (22.8)
5	298 (16.7)
6	378 (21.2)
Worry about being infected with coronavirus disease 2019	
Quite worried	665 (37.3)
Moderately worried	445 (24.9)
Slightly or not worried	674 (37.8)
Optimism about the coronavirus disease 2019 epidemic	
Quite optimistic	908 (50.9)
Moderately optimistic	665 (37.3)
Not optimistic	211 (11.8)
Children's Depression Inventory-Short Form	
Depressive symptoms	403 (22.6)
No depressive symptoms	1381 (77.4)

No anxiety symptoms	1447 (81.1)
Total	1784 (100.0)

Science and Technology. Students completed the investigation through an online crowdsourcing platform (<https://www.wjx.cn/>). The survey link was sent to the guardian's cellular telephone, and the statement "I permit my child to participate in the survey" was presented to the guardian before the survey. The students proceeded to the survey after their guardian had consented. All questionnaires were included in the analysis after a quality audit, with an effective rate of 100.0%.

Information included sex, school grade, optimism about the epidemic, whether they worried about being infected by COVID-19, and depressive and anxiety symptoms measured by the Children's Depression Inventory-Short Form (CDI-S) and the Screen for Child Anxiety Related Emotional Disorders, respectively. Both measures were validated for use in Chinese.¹⁻³ Generalized linear regressions were applied for continuous variables and logistic regressions for binary variables. Results were statistically analyzed with SPSS for Windows 22.0 (IBM). Statistical significance was defined by *P* values less than .05.

Results | Among 2330 students, 1784 participants (1012 boys [56.7%]; 1109 children [62.2%] residing in Huangshi) completed the survey, yielding a response rate of 76.6% (Table 1). Students had been restricted to home for a mean (SD) of 33.7

^a The number and percentage of the students who reported depressive or anxiety symptoms.^b The odds ratios (95% CI) were derived from the binary logistic regression.^c The β values (95% Wald CI) were derived from generalized linear regression (gamma distribution).

(2.1) days when they completed this survey. A total of 403 students (22.6%) and 337 students (18.9%) reported depressive and anxiety symptoms, respectively. Students in Wuhan had significantly higher CDI-S scores than those in Huangshi (β , 0.092 [95% CI, 0.014-0.170]), with a greater risk of depressive symptoms (odds ratio, 1.426 [95% CI, 1.138-1.786]). Students who were slightly or not worried about being affected by COVID-19 had significantly lower CDI-S scores than those who were quite worried (β , -0.184 [95% CI, -0.273 to -0.095]), with a decreased risk of depressive symptoms (odds ratio, 0.521 [95% CI, 0.400-0.679]). Those who were not optimistic about the epidemic, compared with those who were quite optimistic, had significantly higher CDI-S scores (β , 0.367 [95% CI,

0.250-0.485]), with an increased risk of depressive symptoms (odds ratio 2.262 [95% CI, 1.642-3.117]). There was no significant association between demographic characteristics and anxiety symptoms (Table 2).

Discussion | In this study, 22.6% of students reported having depressive symptoms, which is higher than other investigations in primary schools of China (17.2%).⁴ During the outbreak of COVID-19, the reduction of outdoor activities and social interaction may have been associated with an increase in children's depressive symptoms. Our study found that 18.9% of students reported anxiety symptoms, which is higher than the prevalence in other surveys.⁵ Severe acute respiratory syndrome in 2003 was

also associated with several psychological symptoms among students in China.⁶ These findings suggest that serious infectious diseases may influence the mental health of children as other traumatic experiences do. A limitation is that our current study could not evaluate whether these outcomes will be long-lasting after the COVID-19 outbreak. We will continue to follow up with these participants to improve our understanding about how long those outcomes will last. A better understanding of how the epidemic affects students' mental health can help guide future interventions.

Trends in Marijuana Vaping and Edible Consumption From 2015 to 2018 Among Adolescents in the US

There is growing evidence associating adolescent marijuana use with developmental and societal consequences. Noncombustible marijuana use products are more accessible, but data on use trends compared with smoking marijuana have not been available. Vaping has increased rapidly among adolescents,¹ and although pot brownies are not new, commercially manufactured marijuana edibles are now available. The extent to which these products are used by adolescents nationally is unknown. Regional data suggest boys vape more than girls.²⁻⁴ There are conflicting reports of sex differences in edible use^{4,5} and differences across modes of use for race/ethnicity^{2,4} and socioeconomic status (SES).^{3,4} We document prevalence and trends from 2015 to 2018 in noncombustible marijuana use and differences by use frequency and sociodemographic characteristics (ie, sex, race/ethnicity, SES, and school urbanicity).

Methods | Monitoring the Future data from 2015 to 2018 included 9097 responses from students in 12th grade on relevant forms; 2989 (32.9%) reported using marijuana in the past 12 months, and of these, 2412 (80.7%) had complete data on modes of use and covariates.⁶ The study was approved by the University of Michigan Institutional Review Board, and informed consent (either passive consent or active [ie, written] consent, per school policy) was obtained from parents for students younger than 18 years and from students 18 years or older. A school in more than 90% of the geographic units selected each year to be nationally representative was surveyed; 54 354 of 67 312 selected students (80.7%) responded. Methods of use included smoking, vaping, and edibles. Frequency of past 30-day use was dichotomized to regular/daily marijuana use (20 or more occasions) or less.⁶ Sex (male or female), race/ethnicity (black, white, Hispanic, Asian, or other), parent education as an SES proxy (at least 1 parent has a college degree vs less education), and school urbanicity (urban, suburban, or rural) were examined.

All analyses were conducted in SAS version 9.4 (SAS Institute) using the survey procedures to incorporate the complex sample design and sampling weight, accounting for the differential probability of selection. Wald tests were used to calculate the *P* values, and significance was set as a 2-tailed *P* value less than .05.

Results | In 2018, students reported consuming marijuana through smoking (666 of 746 past-year users [89.3%]; 666 of 2428 students overall [27.4%]), eating (295 of 746 [39.5%]; 295 of 2428 [12.1%]), and vaping (254 of 746 [34.1%]; 254 of 2428 [10.5%]). Among past-year marijuana users from 2015 to 2018, smoking decreased (2015, 643 of 679 [94.7%]; 2018, 666 of 746 [89.3%]), while eating (2015, 217 of 679 [32.0%]; 2018, 295 of 746 [39.5%]) and vaping (2015, 179 of 679 [26.4%]; 2018, 254 of 746 [34.1%]) increased (**Figure**). In 2018, consuming mari-
